Liquid Argon TPC

Anode wire planes:

U V Y

Cathode Plane

Then ionized electrons are drifted to anode wires (~ms)

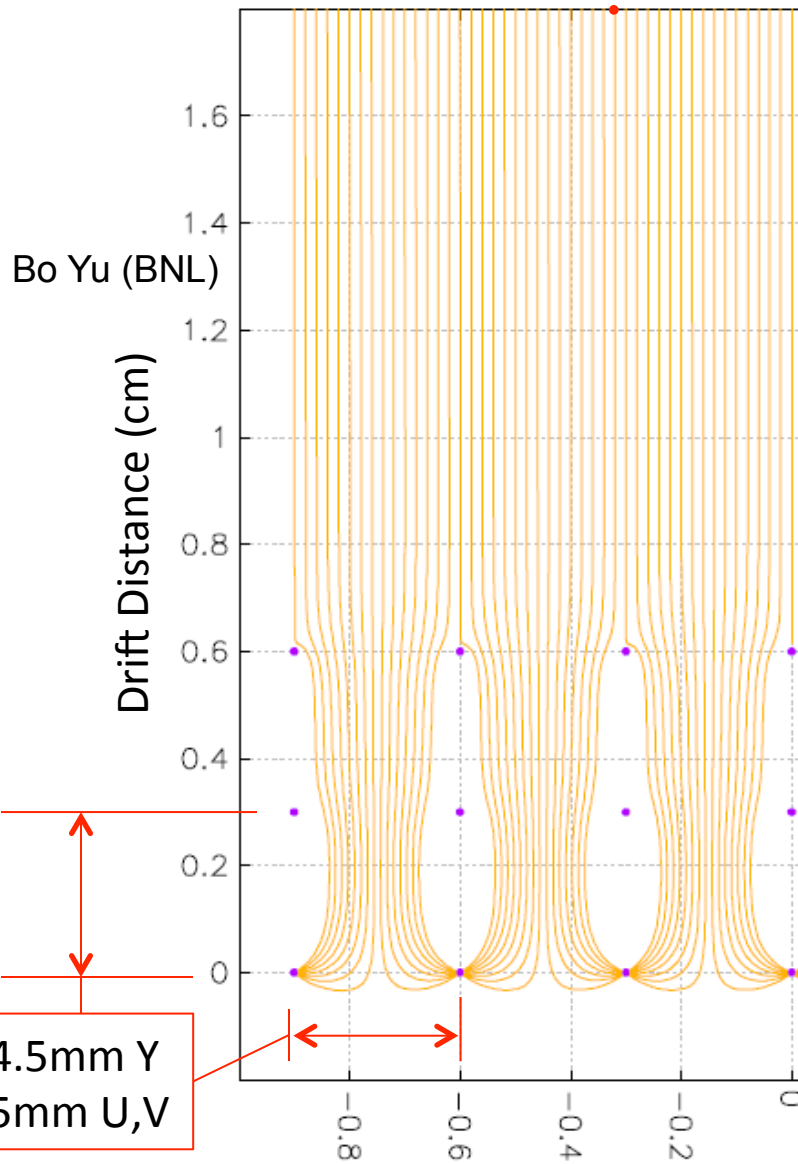

Electrons near the wires are collected first, and electrons far from the wires are collected last, so drift coordinate information is converted to electron drift time (time is projected)

$E_{\text{drift}} \sim 500\text{V/cm}$

## LBNE prototype cryostat exceeds goals

Scientists and engineers working on the design of the particle detector for the Long-Baseline Neutrino Experiment (LBNE) celebrated a major success in January. They showed that very large cryostats for liquid-argon-based neutrino detectors can be built using

The LBNE prototype cryostat

industry-standard technology normally employed for the storage of liquefied natural gas. The 35-tonne prototype system satisfies LBNE's stringent purity requirement on oxygen contamination in argon of less than 200 parts per trillion (ppt) – a level that the team could maintain stably.

The purity of liquid argon is crucial for the proposed LBNE time-projection chamber (TPC), which will feature wire planes that collect electrons from an approximately 3.5 m drift region. Oxygen and other electronegative impurities in the liquid can absorb ionization electrons created by charged particles emerging from neutrino interactions and prevent them from reaching the TPC's signal wires.

The test results were the outcome of the first phase of operating the LBNE prototype cryostat, which was built at Fermilab and features a membrane designed and supplied by the IHI Corporation of Japan. As part of the test, engineers cooled the system and filled the cryostat with liquid argon without prior evacuation. On 20 December, during a marathon 36 hour session, they cooled the membrane cryostat slowly and smoothly to 110 K, at which point they commenced the transfer of some 20,000 litres of liquid argon, maintained at about 89 K, from Fermilab's Liquid Argon Purity Demonstrator to the 25 tonne cryostat

TABLE 1 Summary of Scenarios A, B, and C. Each major project considered by P5 is shown, grouped by project size and listed in time order based on year of peak construction. Project sizes are: Large (>\$200M), Medium (\$50M-\$200M), and Small (<\$50M). The science Drivers primarily addressed by each project are also indicated, along with the Frontier technique area (E-Energy, I-Intensity, C-Cosmic) defined in the 2008 P5 report.

## Neutrino beam 'major physics experiment'

1 hour ago

The UK will be part of what is being described as one of the biggest physics experiments ever built, in an effort to learn more about the creation of the universe.

Researchers will fire a beam of particles called neutrinos through 1,300km (800 miles) of rock - from their lab near Chicago to a location in South Dakota.

The UK's role in the \$1.5bn (£1bn) project will be to help to build a giant neutrino detector, likely to be about 12m (39ft) across.

Studying how the particles change as they travel will give a deeper

4. Challenge of LArTPC technology
5. Conclusion

### 3. Scintillation light from argon

#### Noble gas comparison

- lower boiling point is easier to handle
- higher density has more energy deposit
- longer wavelength is easier to detect
- Xe>Kr>Ar>Ne>He but Xe and Kr are expensive

	He	Ne	Ar	Kr	Xe	Water
Boiling Point [K] @ 1atm	4.2	27.1	87.3	120.0	165.0	373
Density [g/cm <sup>3</sup> ]	0.125	1.2	1.4	2.4	3.0	1
Radiation Length [cm]	755.2	24.0	14.0	4.9	2.8	36.1
Scintillation [ $\gamma$ /MeV]	19,000	30,000	40,000	25,000	42,000	
dE/dx [MeV/cm]	0.24	1.4	2.1	3.0	3.8	1.9
Scintillation $\lambda$ [nm]	80	78	128	150	175	

### 3. Scintillation light from argon

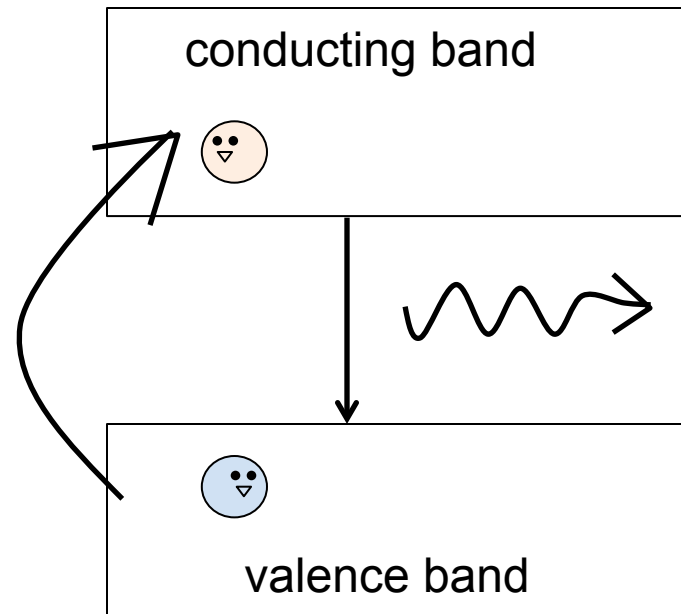

#### Argon as gas scintillator

Organic scintillator (PPO, POPOP, PBD, etc)

- S0-S1 excitation of  $\pi$ -electron

Inorganic scintillator (NaI(Tl), etc)

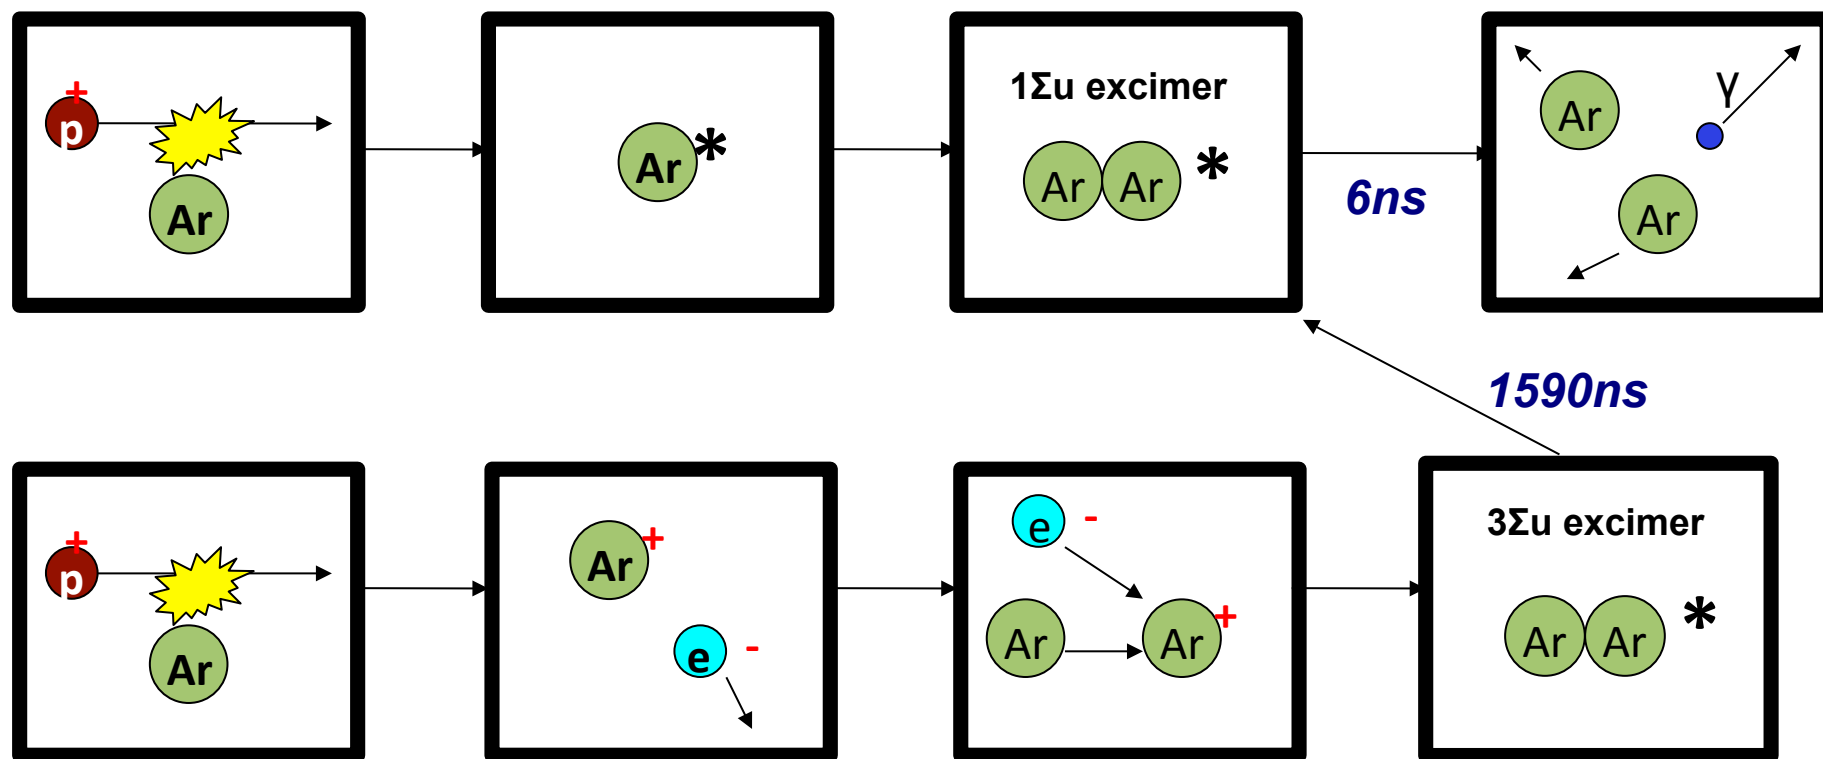

- Crystal with impurity

### 3. Scintillation light from argon

#### Argon as gas scintillator

- 2 excitation path, singlet (spin 0) and triplet (spin 1)
- prompt signal can be used for trigger
- delayed signal is sensitive to impurity (nitrogen)
- both vacuum UV (128nm)

### 3. Scintillation light from argon

#### Argon as gas scintillator

- 2 excitation path, singlet (spin 0) and triplet (spin 1)
- prompt signal can be used for trigger
- delayed signal is sensitive to impurity (nitrogen)
- both vacuum UV (128nm)

# 3. Scintillation light from argon

TPB (tetraphenyl butadiene)

- convert 128nm to blue (efficiency > 100%?!)
- degrade by UV light (possibly by humidity, too)

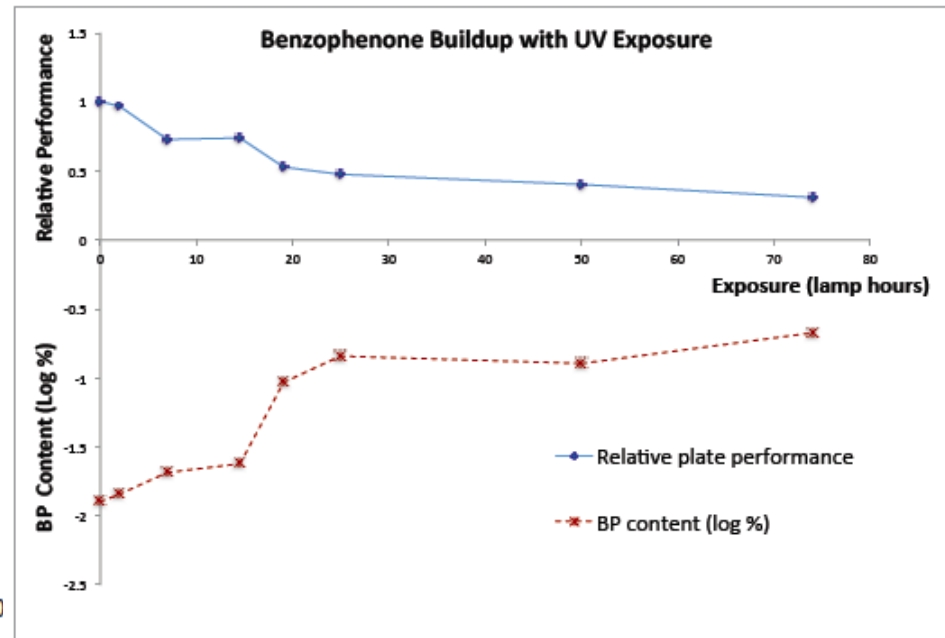

TPB plate performance degradation

Chiu et al., JINST7(2012)P07007

Benzophenone production

Jones et al., JINST8(2013)P01013

### 3. Scintillation light from argon

#### TPB plate idea

- deposit TPB-polystyrene mixture on acrylic plate (TPB plate)
- equip TPB in front of PMT

Mechanical model of  
MicroBooNE PMT

TPB plate sample

Lab6 scintillation building

### 3. Scintillation light from argon

#### TPB plate idea

- deposit TPB-polystyrene mixture on acrylic plate (TPB plate)
  - equip TPB in front of PMT
  - performance of TPB plate is measured by vacuum spectrometer.
- Comparing with vacuum evaporated plate, it is ~OK

#### Deuterium lamp spectrum

#### Fermilab vacuum spectrometer

### 3. Scintillation light from argon

#### TPB plate idea

- deposit TPB-polystyrene mixture on acrylic plate (TPB plate)
  - equip TPB in front of PMT
  - performance of TPB plate is measured by vacuum spectrometer.
- Comparing with vacuum evaporated plate, it is ~OK

#### TPB plate performance

### 3. Scintillation light from argon

#### Impurity measurement

- $O_2$  and  $N_2$  are known impurity to reduce scintillation output
- Nitrogen is not controlled in LArTPC experiment (oxygen is <ppb to make TPC works)
- Nitrogen injection line and monitor is installed in Bo cryostat system

# 3. Scintillation light from argon

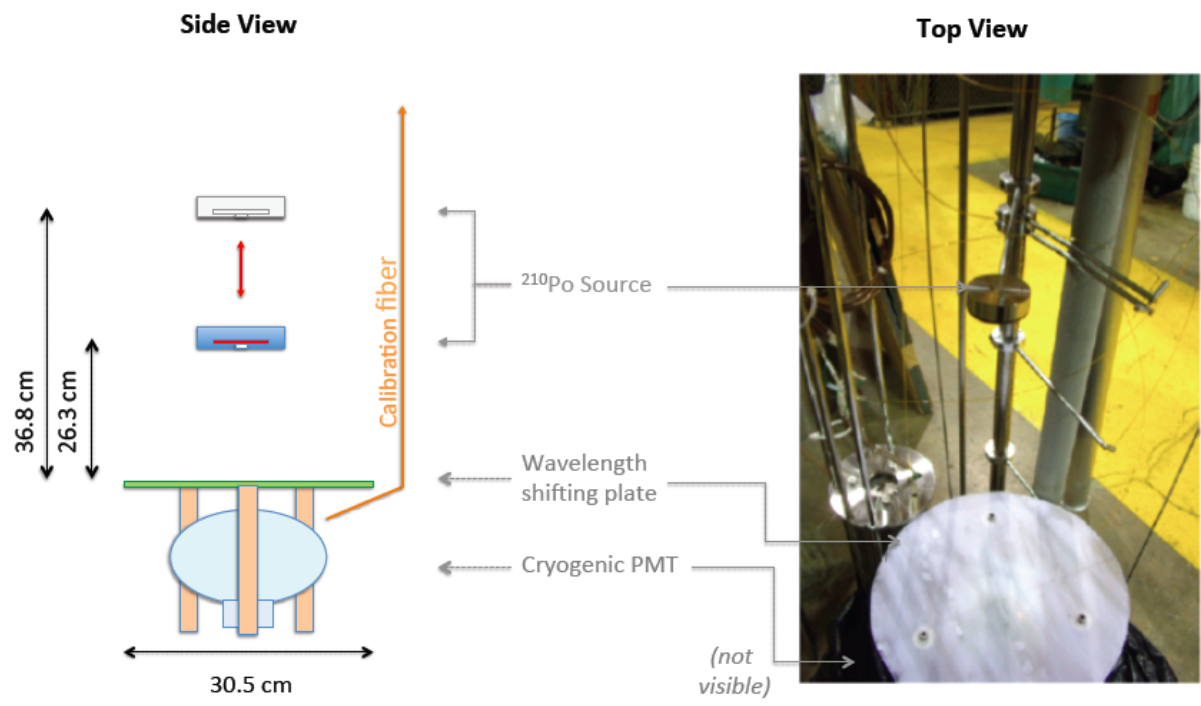

## Impurity measurement

- O<sub>2</sub> and N<sub>2</sub> are known impurity to reduce scintillation output
- Nitrogen is not controlled in LArTPC experiment (oxygen is <ppb to make TPC works)
- Nitrogen injection line and monitor is installed in Bo cryostat system

### 3. Scintillation light from argon

#### Impurity measurement

- $O_2$  and  $N_2$  are known impurity to reduce scintillation output
- Nitrogen is not controlled in LArTPC experiment (oxygen is <ppb to make TPC works)
- Nitrogen injection line and monitor is installed in Bo cryostat system
- LAr with “typical”  $N_2$  impurity has negligible effect on attenuation

Light output from  $^{210}\text{Po}$

Argon Specification	Concentration of $N_2$	Absorption Length
Measured $N_2$ concentration of clean argon for this study	37 ppb	$1790 \pm 160$ m
AirGas research (grade 6) argon [25]	1 ppm	$66 \pm 6$ m
MicroBooNE cryogenic specification	2 ppm	$30 \pm 3$ m
Start of liquid recirculation phase of Liquid Argon Purity Demonstrator, Run 2 [26, 27]	8 ppm	$8.2 \pm 0.7$ m
AirGas industrial (grade 4) argon [25]	100 ppm	$0.65 \pm 0.06$ m

### 3. Scintillation light from argon

#### Cryogenic PMT

- bi-alkali photo-cathode stops working at  $\sim 150\text{K}$
- Pt-coating to save electron mobility (1<sup>st</sup> generation cryogenic PMT)
  - slight loss of quantum efficiency
- super bi-alkali works in cold (2<sup>nd</sup> generation cryogenic PMT)
- base circuit should avoid temperature dependent components
- heat deposit  $\sim 0.5\text{W}/\text{base}$

MicroBooNE PMT base

### 3. MicroBooNE PMT test stand

Open Dewar based PMT test stand

### PMT TEST STAND

### 3. MicroBooNE PMT test stand

#### Open Dewar based PMT test stand

- All structures are attached on glass fiber lid
- there are 5 penetrations
  - LN2 injection
  - gas vent
  - level sensor
  - cable feed-through
  - light injection system
- In room temperature, PMTs sit on Delrin bottom fixture
- In LN2, PMTs float and fit in Delrin upper fixture
- There is a weight at the bottom of the structure

## 3. MicroBooNE PMT test stand

### Open Dewar based PMT test stand

#### Purpose

- All PMTs need to be operated in cryogenic temperature before the experiment
- Verify spec gain and dark current in cryogenic condition
- Gain experiences of cryogenic PMT operation
- Study basic features (how long do you need to cool down, etc)

No need to be pressurized vessel (expensive, safety issue)

#### Large open Dewar with modification

- commercial open Dewar, 346L (70cmx90cm inner diameter and height), \$17,000
- Labor + Materials ~ \$5000
- Total \$22,000
- Need 1 or 2 of 160L LN2 bottle to fill every week (LN2~\$30, LAr~\$160)
- No need technician's help for operation

#### Test procedure

- 4 PMTs are simultaneously immersed in LN2
- 1 PMT (calibration PMT) stays same location during all tests
- PMTs are immersed in LN2 least 3 days with dark before any tests
- LED illumination + trigger in LN2 (no purity issue)

### 3. MicroBooNE PMT test stand

#### Open Dewar based PMT test stand

- Dark current and gain are measured both in air and liquid nitrogen (LN2).
- Operation HV values in cryogenic temperature are extracted.

Typical warm and cold gain

Gains are measured at every 100V from 900V to 1800V.

PMT cold gains are ~10-50% of warm gains.

Optimal HV value for  $3E7$  gain is extrapolated.

### 3. MicroBooNE PMT test stand

#### Open Dewar based PMT test stand

- Dark current and gain are measured both in air and liquid nitrogen (LN2).
- Operation HV values in cryogenic temperature are extracted.

#### Optimal HV distribution for 3E7 gain

Gains are measured at every 100V from 900V to 1800V.

PMT cold gains are ~10-50% of warm gains.

Optimal HV value for 3E7 gain is extrapolated.

~200 V increase can recover gain drop

### 3. MicroBooNE PMT test stand

#### Open Dewar based PMT test stand

- Dark current and gain are measured both in air and liquid nitrogen (LN2).
- Operation HV values in cryogenic temperature are extracted.

Cold dark current is slightly higher than warm dark current.

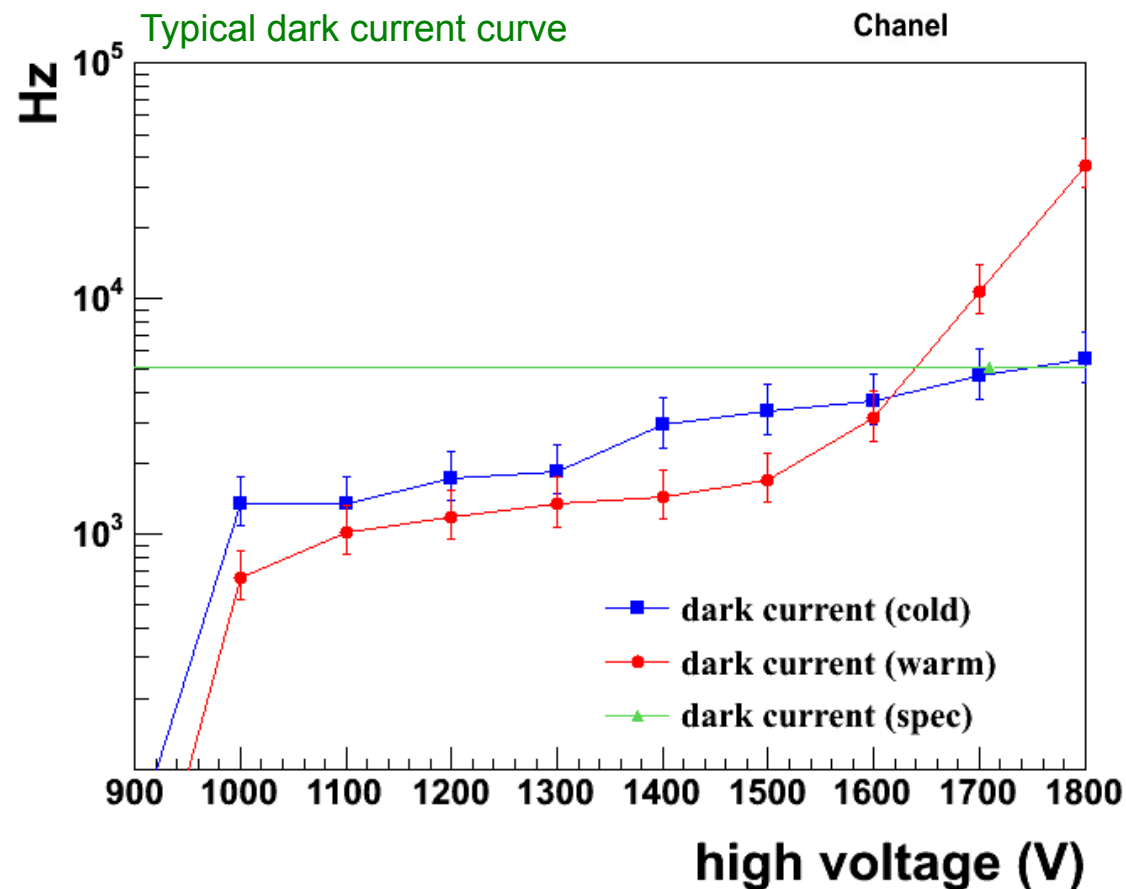

Cold noise doesn't show "plateau break down" at higher HV.

These results are not intuitive, but in fact well known.

### 3. MicroBooNE PMT array system

#### 32 PMTs with 4 light guides

- PMT sits in spring-loaded structure
- avoid direct glass-metal contact by teflon
- cryogenic magnetic shield

### 3. Light guide

#### TPB coated acrylic bar

- TPB re-emitted light is trapped in acrylic bar, and internally reflect
- Collected by photo-sensor (2-inch PMT) at the end
- The concept works, efficiency seems low
- MicroBooNE has 4 of them to compare performance with 8-inch PMTs

LBNE APA concept  
Anode Plane Assembly  
conceptual design. Wires  
are wrapping around a light  
guide

## 3. Light guide

### TPB coated acrylic bar

- TPB re-emitted light is trapped in acrylic bar, and internally reflect
- Collected by photo-sensor (2-inch PMT) at the end
- The concept works, efficiency seems low
- MicroBooNE has 4 of them to compare performance with 8-inch PMTs

### Initial light guide test results

- The basic idea works
- Efficiency is rather low ( $\sim 0.1\%$ )
- Lots of room to improve
  - better quality of acrylic
  - better TPB deposition technique

### Long Bo

- Indiana university further improved this technique, and tested

### LBNE35ton

- It will equipped one of these

1. Introduction
2. US LArTPC programs
3. LAr photon detection R&D
- 4. Challenge of LArTPC technology**
5. Conclusion

## 4. Challenge of LArTPC technology

### Cosmic rays

- Cosmic rays of MicroBooNE is  $\sim 10\text{kHz}$
- MicroBooNE DAQ windows is  $\sim 1.6\text{ ms}$
- $\sim 20$  cosmic rays across the detector in the DAQ window
- Reconstruction program needs to find true neutrino interaction and tracks successfully
- Combination of PMT and TPC information can find all cosmic rays efficiently

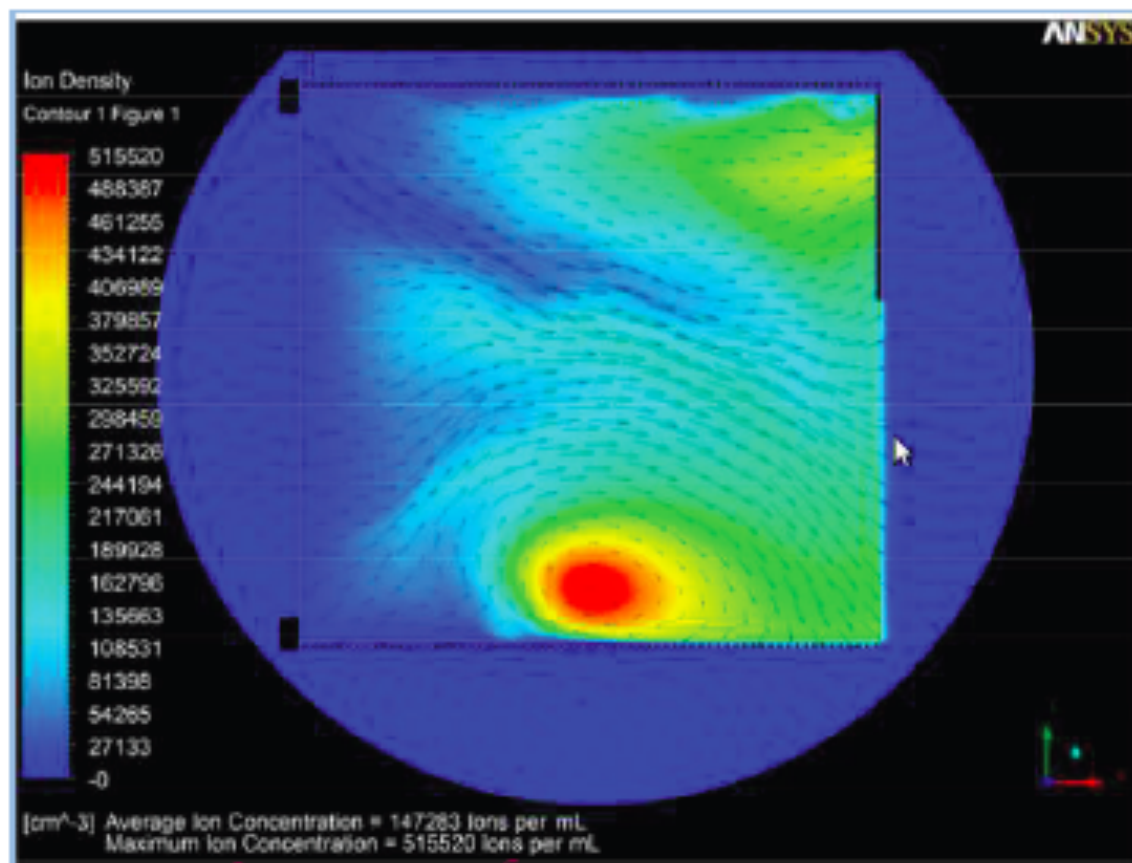

Simulated MicroBooNE event, reconstructed in 3D

## 4. Challenge of LArTPC technology

### Positive ion problem

- Cosmic rays of MicroBooNE is  $\sim 10\text{kHz}$
- They produce tons of argon ions
- Speed of argon ions ( $\sim \text{cm/s}$ )  $<$  liquid argon flows
- Vortex of liquid argon flow behave like a “sink” of positive ions
- Electric field inside of the TPC is never straight

## 4. Challenge of LArTPC technology

### Positive ion problem

- Cosmic rays of MicroBooNE is  $\sim 10\text{kHz}$
- They produce tons of argon ions
- Speed of argon ions ( $\sim \text{cm/s}$ )  $<$  liquid argon flows
- Vortex of liquid argon flow behave like a “sink” of positive ions
- Electric field inside of the TPC is never straight

### Con – ICARUS surface running

- ICARUS took cosmic ray data on surface, and it shows perfect parallel lines of comic rays, showing electric field is uniform across the detector
- ICARUS and MicroBooNE has different cryostat, cooling, flow system, etc

To manage field distortion, MicroBooNE has a laser calibration system.

We will find out this effect from MicroBooNE data

How about LBNE?

## 4. Challenge of LArTPC technology

### High voltage system

- MicroBooNE need to drift 2.5m
- Drift velocity is chosen to be same with ICARUS (1.5m/ms)
- It requires 500V/cm → 125kV total
- It sounds easy if we trust what textbook said...

Table 3.3 Maximum breakdown strengths of some liquids

Liquid	Maximum breakdown strength (MV/cm)
Hexane	1.1–1.3
Benzene	1.1
Transformer oil	1.0
Silicone	1.0–1.2
Liquid Oxygen	2.4
Liquid Nitrogen	1.6–1.9
Liquid Hydrogen	1.0
Liquid Helium	0.7
Liquid Argon	1.10–1.42

## 4. Challenge of LArTPC technology

### High voltage system

- MicroBooNE need to drift 2.5m
- Drift velocity is chosen to be same with ICARUS (1.5m/ms)
- It requires 500V/cm → 125kV total
- It sounds easy if we trust what textbook said...

MicroBooNE prototype feed-through has a hard time to send 125kV, details of HV break down may depend on many factors (shape and material of feed-through, for example).

if we cannot send 125 kV, MicroBooNE need to run with lower voltage than designed (500V/cm → ?)

- longer drift time (larger DAQ window)
- more cosmic rays in beam window
- more positive ion effect
- more diffusions (worse resolution)
- more recombination (less ionization signal)

MicroBooNE R&D on this topic is critical for future LArTPCs.

# 4. Challenge of LArTPC technology

## Reconstruction

- Event topology is extremely richer than any existing neutrino detectors
- Reconstruction is not easy, sensitivity study is based on MC truth or MC truth with simulated detector effect (called fast MC), to avoid reconstruction
- Otherwise, efficiency is estimated from hand scan

## 4. Challenge of LArTPC technology

### No nuclear model

- In this energy region (<few GeV), nuclear effect is important.
- Argon nucleus is too big to calculate precisely. The best ab initio nuclear model is available only up to  $^{12}\text{C}$ .
- Nuclear model is up to phenomenological one.

MicroBooNE should be able to test these phenomenological models, to reduce errors for future experiments.

## 4. Challenge of LArTPC technology

### NuSTEC (Neutrino scattering Theory-Experiment Collaboration)

NuSTEC is a collaboration of experimentalists and theorists whose mission is to improve neutrino interaction generators, organize workshops to answer community challenges as well as training programs in neutrino nucleus scattering physics and to initiate a global fit of combined results from multiple experiments to theoretical models.

#### NuSTEC training in neutrino-nucleus scattering physics

## Conclusion

LArTPC technology is initiated by ICARUS, and now flourish in US

There are number of projects actively studying LArTPC

MicroBooNE is up coming neutrino beam experiment with LArTPC

All effort focus to the future large LArTPC, such as LBNE

**Thank you for your attention!**
